

Communication base station power generation voltage

Overview

Most telecom base stations use 48V battery systems, while some legacy or hybrid sites may have 24V configurations. Lithium systems can be integrated into these architectures with proper BMS and charge control, providing longer life, reduced weight, and lower maintenance. However, the -48 V DC must first be efficiently converted to a positive intermediate bus voltage before it can be boosted to power the PA or stepped down to a positive workable supply for the digital baseband units (BBU). A power supply with a capacity of 100 W to 350 W was sufficient to cover many. This challenging business environment has spawned new distributed voltage bus standards, such as the recent +12V Intermediate Bus Architecture (IBA). Did you know that 30% of energy loss in telecom grids occurs during power transformation?

With operators spending \$36 billion annually on electricity - equivalent to Denmark's total.
